

# IN5290 Ethical Hacking

---

## Lecture 4: Get in touch with services

Universitetet i Oslo  
Laszlo Erdödi

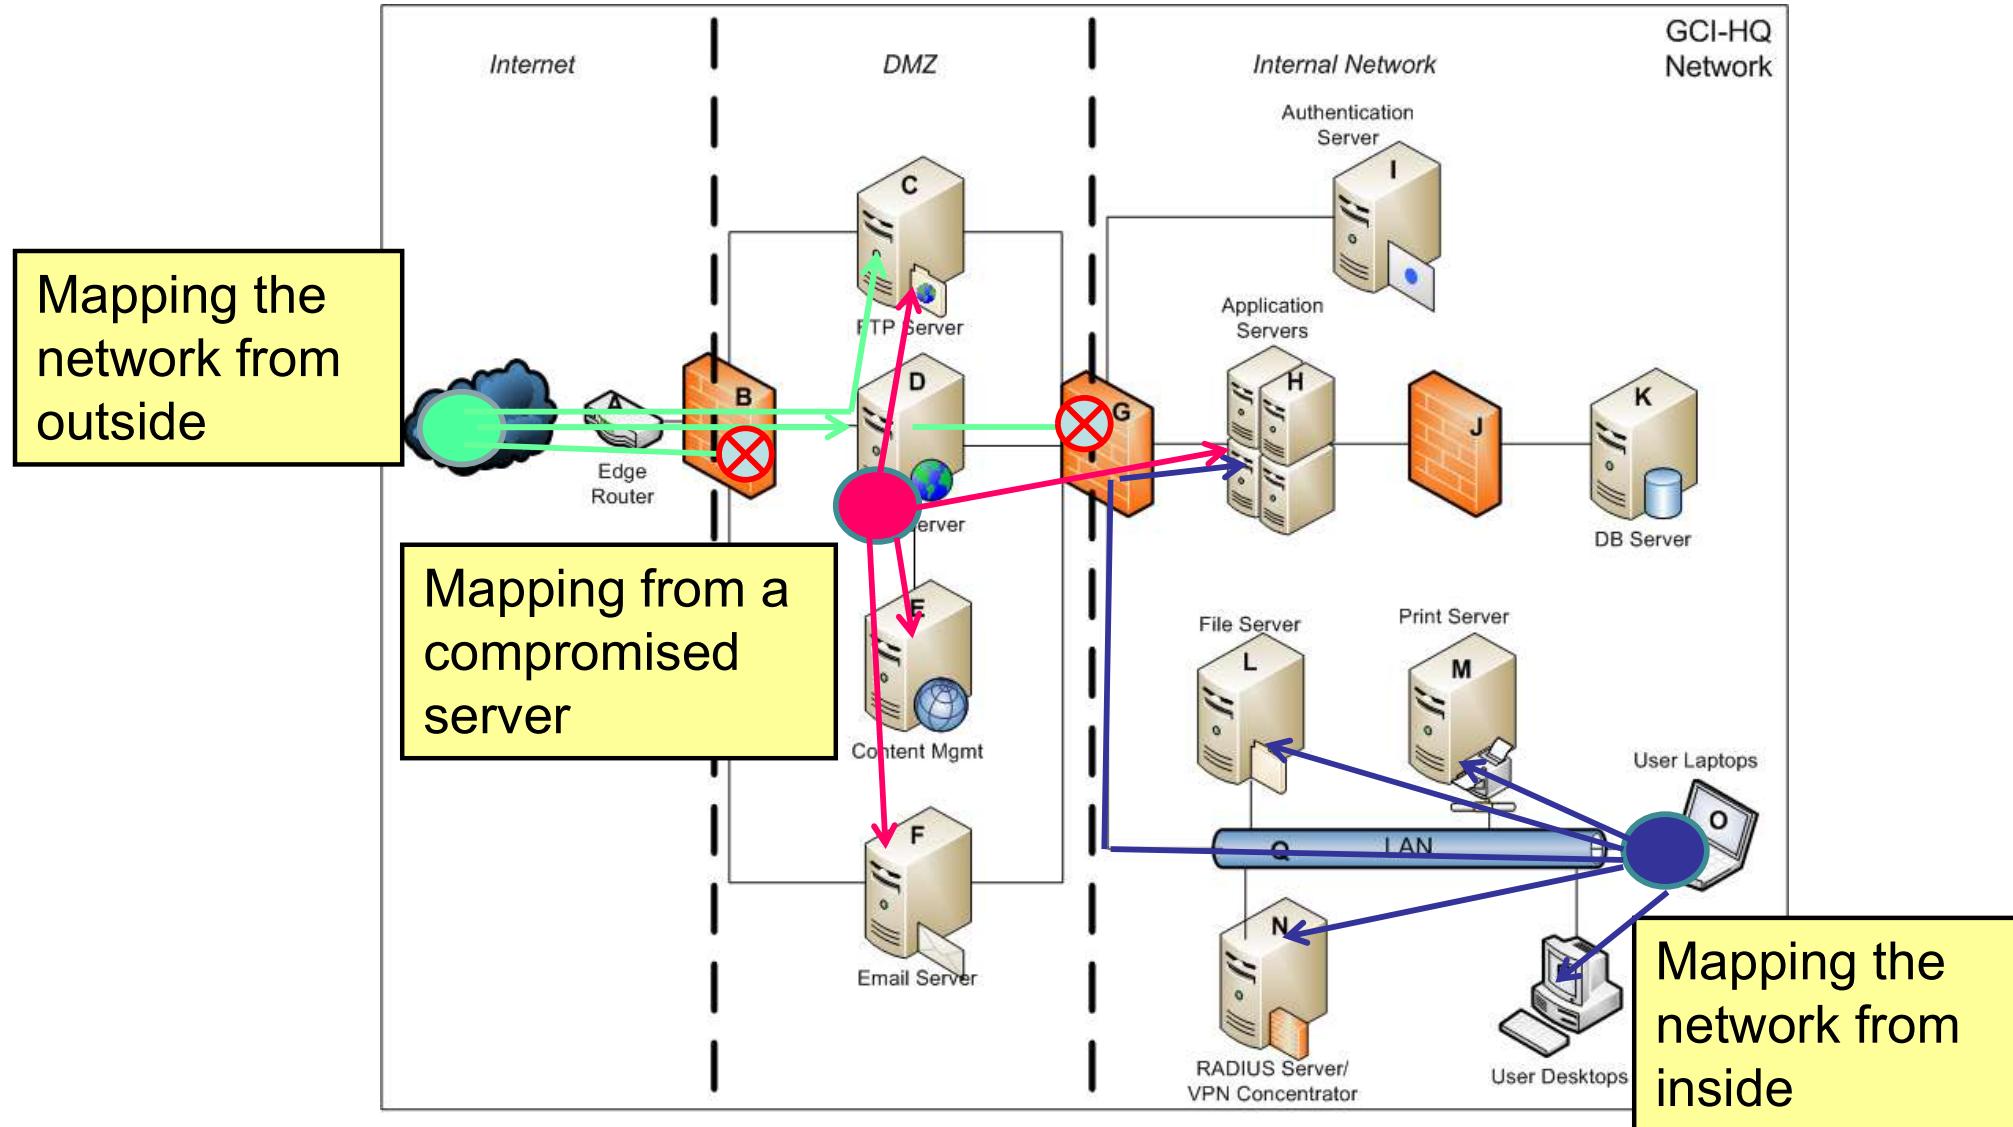

# Lecture Overview

- How to start mapping and compromising a service
- Trying out default credentials
- Brute-forcing techniques and mitigations
- What are the exploits and how to use them
- Using open-relay SMTP
- DNS enumeration and zone transfer

# Where are we in the process of ethical hacking?

- We have several general information about the target
- We have the technical details (domains, ip ranges)
- We mapped the target network and have an inventory (live hosts, responding services)
- What's next?
- We try to compromise services
  - Find a vulnerability
  - Exploit the vulnerability

# Reminder - Network scanning positions

# How to start compromising a service?

What kind of services do we have to face from outside?

Web, Ftp, ssh, dns, mail (SMTP, POP3, IMAP, Exchange),  
VPN and many others

Typical services inside:

Netbios, SMB, Printer, RDP, DB services, LDAP, etc.

# How to start compromising a service?

What kind of errors (vulnerabilities) can we expect?

- Configuration related errors
  - Default credentials
  - Easy to guess credentials (we had information gathering before)
  - No or inappropriate protection against guessing (brute-force)
  - Unnecessary function
  - Privilege misconfigurations
  - Other configuration errors
- Software vulnerability related error
  - No input validation
  - Memory handling errors
  - Several others (see later)

# How to start compromising a service?

- First use in the normal way
  - Is there any information disclosure?
  - Error messages, etc.
  - Restrictions
- Force it to error and obtain information
  - Provide invalid data
  - Use it in an invalid way
- Try factory defaults
- Brute-forcing
- Search for known exploits
- Service specific exploitations
- Unique ways

# Factory defaults

- Default credentials
  - <http://cirt.net>
  - <http://phenoelit.org/dpl/dpl.html>
  - <http://www.defaultpassword.com/>

## Default Passwords

<a href="#">2Wire, Inc.</a>	<a href="#">360 Systems</a>	<a href="#">3COM</a>
<a href="#">3M</a>	<a href="#">Accelerated Networks</a>	<a href="#">ACCTON</a>
<a href="#">Acer</a>	<a href="#">Actiontec</a>	<a href="#">Adaptec</a>
<a href="#">ADC Kentrox</a>	<a href="#">AdComplete.com</a>	<a href="#">AddPac Technology</a>
<a href="#">Adobe</a>	<a href="#">ADT</a>	<a href="#">Adtech</a>
<a href="#">Adtran</a>	<a href="#">Advanced Integration</a>	<a href="#">AIRAYA Corp</a>
<a href="#">Airlink</a>	<a href="#">AirLink Plus</a>	<a href="#">Aironet</a>
<a href="#">Airway</a>	<a href="#">Aladdin</a>	<a href="#">Alcatel</a>
<a href="#">Alien Technology</a>	<a href="#">Allied Telesyn</a>	<a href="#">Allnet</a>
<a href="#">Allot</a>	<a href="#">Alteon</a>	<a href="#">Ambit</a>

- Default functions

# Brute-forcing

- Trying out multiple combinations
- How to generate the options?
  - Random
  - Trying out all combinations
  - Using a list or dictionary
- Brute forcing tools
  - THC Hydra (ssh, ftp, http)  
Hydra was created by a hacker group The Hacker's choice. It is an universal brute-force tool that can be used for several protocols.
  - Ncrack
  - Medusa

# Service specific attacks

We cannot cover all services, but we're going to focus on:

FTP

SSH

SMTP

DNS

Web (Lecture 5,6,7)

Exploits in general (The theory and practice of exploits will be on Lecture 8,9 but we're going to use some of the available exploits now.)

ARP, Netbios, SMB, etc. Lecture 10 (Internal network hacking)

# What is an exploit?

An **exploit** (from the English verb *to exploit*, meaning "to use something to one's own advantage") is a piece of software, a chunk of data, or a sequence of commands that takes advantage of a bug or vulnerability to cause unintended or unanticipated behavior to occur on computer software, hardware, or something electronic (usually computerized). Such behavior frequently includes things like gaining control of a computer system, allowing privilege escalation, or a denial-of-service (DoS or related DDoS) attack.

# Attacking ftp service

The ftp server configuration file declares what is enabled

Example: *vsftpd.conf* file

**anon\_mkdir\_write\_enable**

If set to YES, anonymous users will be permitted to create new directories under certain conditions. For this to work, the virtual users are treated with anonymous (i.e. maximally restricted) privilege.

Default: NO

**anon\_other\_write\_enable**

If set to YES, anonymous users will be permitted to perform write operations other than upload and create directory.

Default: NO

**anon\_upload\_enable**

If set to YES, anonymous users will be permitted to upload files under certain conditions. For this to work, the virtual users are treated with anonymous (i.e. maximally restricted) privilege.

Default: NO

**anon\_world\_readable\_only**

When enabled, anonymous users will only be allowed to download files which are world readable. This is recognition of the fact that anonymous users are not able to upload files.

Default: YES

**anonymous\_enable**

Controls whether anonymous logins are permitted or not. If enabled, both the usernames **ftp** and **anonymous** are accepted.

Default: YES

If anonymous is enabled, we can log in to see what we can do  
We can also brute-force the credentials or use exploits

# Attacking ftp service: anonymous login

```
root@kali:~# ftp 158.36.185.227
Connected to 158.36.185.227.
220 Oh, here it is: UiO-CTF{G00d_0ld_b4nn3rs!}
Name (158.36.185.227:root): anonymous
331 Please specify the password.
Password:
530 Login incorrect.
Login failed.
ftp> ■
```

```
root@kali:~# ftp localhost
Connected to localhost.
220 (vsFTPd 3.0.3)
Name (localhost:root): anonymous
331 Please specify the password.
Password:
230 Login successful.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp> ■
```

If anonymous login is enabled, anyone can log in (username: anonymous, password: arbitrary email)

*anon\_upload\_enable*, *anon\_other\_write\_enable* settings are also important: e.g. if upload is enabled and the webroot is accessible attacking scripts can be uploaded.

# Attacking ftp service: brute-forcing with Hydra

```
root@kali:~# hydra -t 2 -l admin -P pass.lst -vV localhost ftp
Hydra v8.3 (c) 2016 by van Hauser/THC - Please do not use in military or secret service
organizations, or for illegal purposes.

Hydra (http://www.thc.org/thc-hydra) starting at 2018-09-07 07:16:46
[DATA] max 2 tasks per 1 server, overall 64 tasks, 5 login tries (l:1/p:5), ~0 tries per task

- p for single password –P password list (the list file has to be named after)
- t parallel tries (default 16)

# Attacking ftp service: using exploits

The main exploit source is the exploit-db (<http://exploit-db.com>)

And of course the darkweb, if you have needless remaining crypto currencies ☺  
(note that darkweb is not for Ethical Hackers!!!)

# Attacking ftp service: using exploits

Example: *FTPShell Client 6.7 - Buffer Overflow* from May 2018

Theoretically it's not necessary to understand what's happening during the exploitation. The input has to be generated with the provided python script and apply it against the vulnerable service.

Demo...

BUT! This exploit works only for that specific version with the same OS circumstances. E.g. *0x00452eed* has to contain a *call esi* instruction.

Without understanding it you can't customize it.

```
19 buf += "\xdb\xc8\xba\x3e\x93\x15\x8f\xd9\x74\x24\xf4\x5e\x33"

    new_stack += p64(exit_addr)
```

# Attacking SMTP

SMTP (Simple Message Transfer Protocol) is a standard for email transmission in widespread today.

The client logs in to his/hers own server with credentials using SMTP. The mail is forwarded to the receiver's server with SMTP. The receiver downloads the email (e.g. POP3, IMAP).

# Attacking SMTP

The main SMTP commands are:

**HELO**: Sent by a client to identify itself

**EHLO**: The same as HELO but with ESMTP (multimedia support)

**MAIL FROM**: Identifies the sender of the message

**RCPT TO**: Identifies the message recipients

**DATA**: Sent by a client to initiate the transfer of message content

Note there are no *Subject*, *CC*, *BCC* fields. All these data are placed in the data section (these are not part of the smtp)

**VRFY**: Verifies that a mailbox is available for message delivery. If it's allowed user enumeration is possible.

# Attacking SMTP – open relay access

In case of open-relay settings, the user doesn't need to provide credentials. Anyone can send a mail with arbitrary fields. DEMO..

The terminal window shows a root shell on a Kali Linux system. The user runs a telnet session to an SMTP server at IP 41.22.25. The session starts with a connection attempt to port 25, followed by a standard SMTP handshake. The user sends an email from 'paul.mccartney@beatles.com' to 'laszloe@ifi.uio.no'. The message body contains a forged 'From' header and a forged 'To' header, both set to 'paul.mccartney@beatles.com'. The message content is a friendly greeting.

The Outlook Web App inbox shows a new email from 'paul.mccartney@beatles.com'. The subject is '(Mangler emne)'. The body of the email reads: 'Hi Laszlo, Beatles will be reunited. Sincerely, Paul'. The timestamp on the email is 11:41.

# Attacking SMTP – open relay access

How to find open-relay SMTP?

- If one of the client's SMTP allows open-relay access then any email can be written unseeingly
- Spamboxes will probably contain some open-relay SMTP server 😊

How can the users make sure that an email arrived from the right person?

- Check the email header
- There's no 100% guarantee, use PGP (mail encryption)! 😊

# Attacking SMTP – open relay access

## Checking the email header

(Mangler emne)

The screenshot shows an email client interface. At the top, there's a small message preview for an email from 'paul.mccartney@beatles.com' sent on '09.09.2018 11:41'. Below this, the main body of the email contains a message from 'Hi Laszlo,' followed by 'Beatles will be reunited.' and 'Sincerely, Paul'. To the right, a large modal window titled 'Meldingsinformasjon' displays the message headers. A red box highlights the 'X-UIC-Spam-info' line, which reads: 'not spam, SpamAssassin (score=0.9, required=5.0, autolearn=disabled, MISSING\_HEADERS=0.915, MISSING\_SUBJECT=0.001, uiobl=NO, uiouri=NO)'. The rest of the headers listed include X-UiO-Scanned, To, Return-Path, MIME-Version, Content-Type, X-MS-Exchange-Organization-Network-Message-Id, X-MS-Exchange-Organization-AVStamp-Enterprise, X-MS-Exchange-Organization-AuthSource, and X-MS-Exchange-Organization-AuthAs. To the right of the modal, another window titled 'Meldingsinformasjon' shows the full received chain of the email, starting with 'Received: from mail-ex14.exprod.uio.no (2001:00:100:120::/6)' and ending with 'Received: by sendmail [REDACTED] (Postfix, from userid 35)'. Both windows have a 'Lukk' button at the bottom right.

paul.mccartney@beatles.com  
09.09.2018 11:41

Hi Laszlo,  
Beatles will be reunited.  
Sincerely,  
Paul

# Email– brute force with THC-Hydra

```
hydra smtp.victimsemailserver.com smtp -l  
victimaccountname -P 'pass.lst' -s portnumber -S -v -V
```

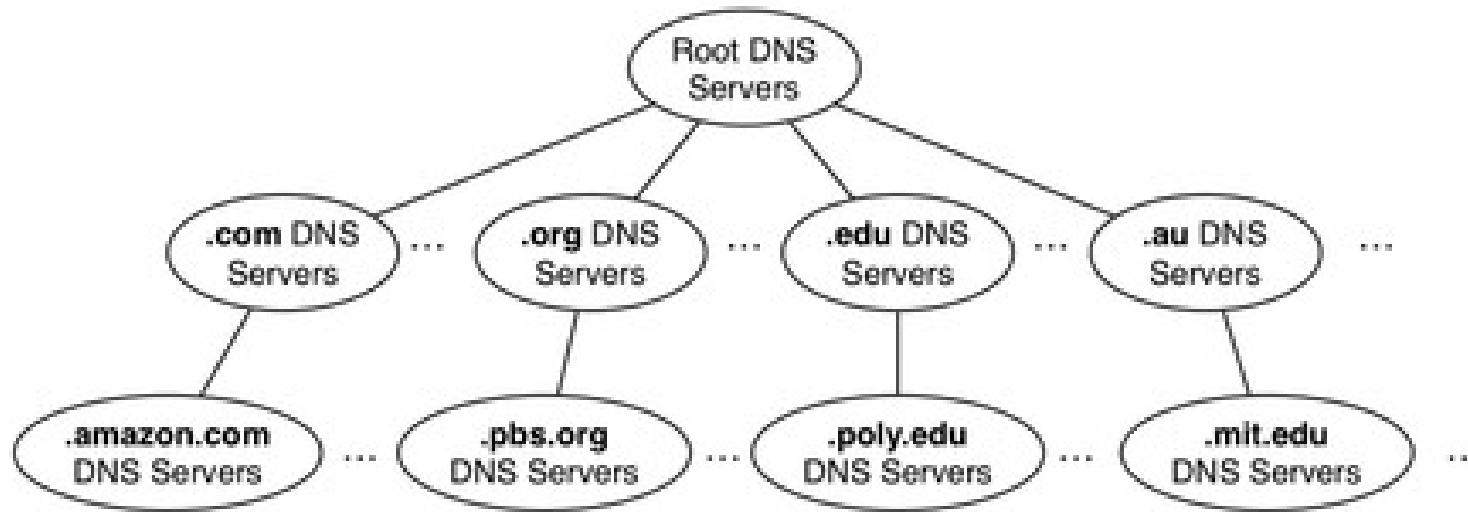

```
hydra -l username -P pass.txt my.pop3.mail pop3
```

```
hydra -L userlist.txt -p defaultpw imap://192.168.0.1/PLAIN
```

# Supported protocols by THC-Hydra

Asterisk, AFP, Cisco AAA, Cisco auth, Cisco enable, CVS, Firebird, FTP, HTTP-FORM-GET, HTTP-FORM-POST, HTTP-GET, HTTP-HEAD, HTTP-POST, HTTP-PROXY, HTTPS-FORM-GET, HTTPS-FORM-POST, HTTPS-GET, HTTPS-HEAD, HTTPS-POST, HTTP-Proxy, ICQ, IMAP, IRC, LDAP, MS-SQL, MYSQL, NCP, NNTP, Oracle Listener, Oracle SID, Oracle, PC-Anywhere, PCNFS, POP3, POSTGRES, RDP, Rexec, Rlogin, Rsh, RTSP, SAP/R3, SIP, SMB, SMTP, SMTP Enum, SNMP v1+v2+v3, SOCKS5, SSH (v1 and v2), SSHKEY, Subversion, Teamspeak (TS2), Telnet, VMware-Auth, VNC and XMPP.

# DNS service

- DNS servers are all around the world
- Organized in tree structure (13 root servers)
- The top level domains (.com, .net, .edu, .no, .de, etc.) are directly under the root servers
- DNS data are stored redundantly (master and slave server)

# Attacking DNS – zone transfer

Since DNS data is stored redundantly the slave DNS can ask the master DNS to send a copy of a part of its database (zone) to the slave.

Zone transfer operation should be limited for the slave ip address. If this is not the case, anyone can obtain the whole zone data (and network topological information too).

# Attacking DNS – domain brute-forcing

See more: <https://pentestlab.blog/tag/domain-brute-force/>  
<https://github.com/rbsec/dnscan>

<a href="#">dns.py</a>	Fix Spelling mistake leads to program not being compiled
<a href="#">requirements.txt</a>	Add requirements.txt file for installing deps
<a href="#">subdomains-100.txt</a>	Updated subdomain lists
<a href="#">subdomains-1000.txt</a>	Lowecase the subdomain files and remove a few dupes.
<a href="#">subdomains-10000.txt</a>	Added a few more common subdomains
<a href="#">subdomains-500.txt</a>	Updated subdomain lists
<a href="#">subdomains-uk-1000.txt</a>	Lowecase the subdomain files and remove a few dupes.
<a href="#">subdomains-uk-500.txt</a>	Added .uk subdomain lists
<a href="#">subdomains.txt</a>	Added a few more common subdomains
<a href="#">suffixes.txt</a>	Remove suffix that creates wildcards

```
root@kali:~# dnsrecon -d www.uio.no -D /root/subdomains-500.txt -t brt
[*] Performing host and subdomain brute force against www.uio.no
[*] 0 Records Found
root@kali:~#
```

# Nmap scripting engine, Medusa

- **Default category:** checks for factory defaults

<code>dns-nsid</code>	Retrieves information from a DNS nameserver by requesting its nameserver ID (nsid) and asking for its id.server and version.bind values. This script performs the same queries as the following two dig commands: - dig CH TXT bind.version @target - dig +nsid CH TXT id.server @target
<code>dns-recursion</code>	Checks if a DNS server allows queries for third-party names. It is expected that recursion will be enabled on your own internal nameservers.
<code>dns-service-discovery</code>	Attempts to discover target hosts' services using the DNS Service Discovery protocol.
<code>epmd-info</code>	Connects to Erlang Port Mapper Daemon (epmd) and retrieves a list of nodes with their respective port numbers.
<code>finger</code>	Attempts to retrieve a list of usernames using the finger service.
<code>flume-master-info</code>	Retrieves information from Flume master HTTP pages.
<code>freelancer-info</code>	Detects the Freelancer game server (FLServer.exe) service by sending a status query UDP probe.
<code>ftp-anon</code>	Checks if an FTP server allows anonymous logins.
<code>ftp-bounce</code>	Checks to see if an FTP server allows port scanning using the FTP bounce method.
<code>ftp-systat</code>	Sends FTP SYST and STAT commands and returns the results

- **Brute category:** carry out brute-forcing with multiple protocols
- **Vuln category:** tries to identify vulnerabilities
- **Auth category:** authentication bypass, etc.

**Medusa** is a speedy, massively parallel, modular, login brute-forcer. It supports many protocols: AFP, CVS, FTP, HTTP, IMAP, rlogin, SSH, Subversion, and VNC, etc.

# Ncrack

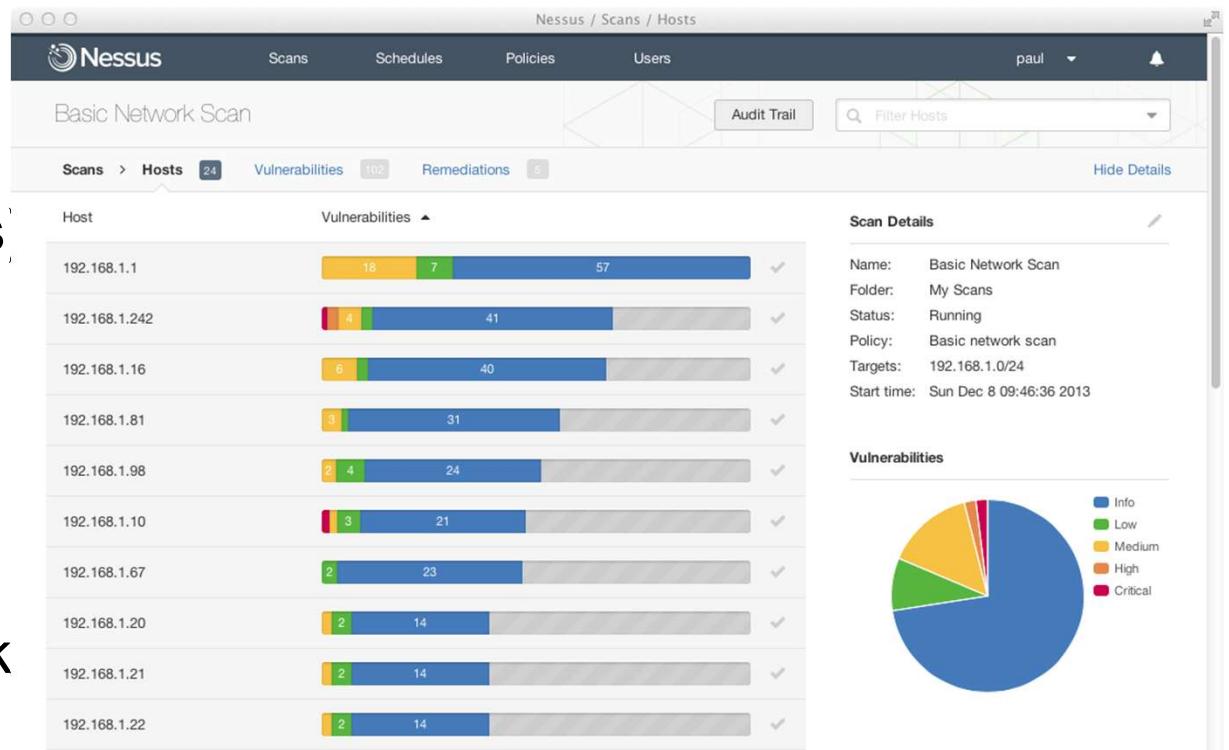

- Ncrack is a high-speed network authentication cracking tool. Ncrack was designed using a modular approach, a command-line syntax similar to Nmap and a dynamic engine that can adapt its behavior based on network feedback. It allows for rapid, yet reliable large-scale auditing of multiple hosts.
- Ncrack's features include full control of network operations, allowing for very sophisticated brute-forcing attacks, timing templates for ease of use, runtime interaction similar to Nmap's and many more. Protocols supported include SSH, RDP, FTP, Telnet, HTTP(S), POP3(S), IMAP, SMB, VNC, SIP, Redis, PostgreSQL, MySQL, MSSQL, MongoDB, Cassandra, WinRM and OWA.

# Get in touch with services, what's the order?

The order of the investigation is the following:

- Manual analysis (initial)
- Automatic analysis  
(several prewritten scripts)  
There are several tools  
to analyze the services  
automatically. E.g.  
Nessus, OpenVAS,  
Qualys, etc..
- Manual analysis (to check  
for false positives)
